FINDING 1: STATIONARY PERSISTENT OBJECTS

Proposed False Claims Act Disclosure

Three Stationary Persistent Objects (SPOs) were documented during the reporting period. These objects remained observable over multiple observation sessions while maintaining a relatively consistent apparent position with respect to surrounding celestial reference points. For organizational purposes, these recurring observations are designated SPO-A, SPO-B, and SPO-C.

These designations refer to recurring observational patterns rather than confirmed physical objects. During at least one documented observation, two stationary-appearing objects were observed simultaneously in close proximity. One object appeared to move toward the other before one was no longer visible and the remaining object continued to occupy approximately the same apparent region of the sky. Based on that observation, I cannot conclude that an object observed in the same apparent location on different dates necessarily represents the same physical object. Accordingly, the terminology used throughout this report identifies recurring observational patterns rather than asserting continuous object identity. What has remained consistent is not necessarily a single object, but the continued occupation of the same general apparent location in the sky.

From the first documented SPO observation in November 2025 through the conclusion of this reporting period, at least one Stationary Persistent Object has been observable on every clear-sky observation night, without interruption. Individual SPOs did not remain observable indefinitely; each was documented over a finite period before it was no longer observed. However, before an existing SPO ceased to be observed, a subsequent object exhibiting substantially similar characteristics was typically already observable, producing an overlapping transition rather than a gap in observable presence. During at least one such transition, two SPOs were documented within the same photographic frame over a period of several weeks before one was no longer observed.

SPO-A was first documented in November 2025 and remained observable through approximately early July 2026. Throughout that period, the object was repeatedly documented from the primary observation location and is referenced throughout the chronology.

SPO-B was first documented in December 2025 and remained observable until approximately early April 2026. Its period of observation overlapped with SPO-A before it was no longer observed.

SPO-C was first documented during travel between North Carolina and Arizona in March 2026. Following the return to North Carolina, an object exhibiting substantially similar observational characteristics was documented from the primary observation location and remained observable through the conclusion of this reporting period, overlapping with SPO-A for a period of several weeks.

The chronology documents these overlapping and sequential periods of observation in detail. These observations are presented chronologically to preserve the sequence in which they occurred.

This finding summarizes the recurring, continuous presence of Stationary Persistent Objects documented throughout the investigation. Detailed observational records, photographs, videos, and supporting documentation are contained within the chronology and accompanying exhibits.
